

Lesson 1: From Blocks to Words — Hello, Python!

Welcome, Young Builder!

Remember in Scratch, when you clicked the green flag and your sprite said **"Hello!"**? You built that by snapping together colorful blocks.

Today you're going to learn something amazing: computers can understand **typed words** too! This is called **Python** — it's a real programming language used by grown-up coders all over the world, and now YOU get to use it.

Think Like a Coder

A Scratch "say" block and a Python `print()` command do the **exact same job** — they both make words show up. The only difference is *how* we tell the computer to do it: blocks vs. typed text.

Step 1: Open Thonny

1. Open the **Thonny** app (or your Repl.it project).
2. You'll see two boxes: - The **top box** (editor) is where you type your code. - The **bottom box** (shell) is where your messages appear.

Step 2: Type Your First Line of Code

Click in the editor and type this exactly:

```
print("Hello, world!")
```

Step 3: Run It!

Press the green **Run** button (or the F5 key). Look at the bottom box — you should see:

```
Hello, world!
```

🎉 You just wrote and ran your first Python program!

Robot Tip

Python is very exact. It needs: - **Quotes** " " around any words you want it to show. - **Parentheses** () around what goes inside `print`.

Miss one, and Python gets confused!

Step 4: Add More Lines

Try typing this whole program:

```
print("Hello, world!")
print("My name is Python, and I love to help you build things!")
```

Run it and watch both lines appear in the shell.

Mini Challenge

Change the message so it says hello using **your own name**. For example:

```
print("Hello, my name is Maya!")
```

Run it and see your own greeting appear!

Debug Detective

Uh-oh! This code has a bug in it. Can you find what's wrong?

```
print("Hello, world!)
```

Hint: count the quote marks. 🧑

The Fix:

```
print("Hello, world!")
```

There was a missing closing quote `"` before the closing parenthesis. Python needs a quote at the **start** and the **end** of your text.

★ Bonus Challenge

Can you use several `print()` lines to draw a tiny picture out of letters and symbols? Try this rocket:

```
print("  /\  ")
print(" /  \ ")
print("|    | ")
print("|PYTHON|")
print("/_____\")
```

🎨 Make It Yours

Write three `print()` lines that tell us about YOU — your name, your favorite color, and your favorite animal. Example:

```
print("My name is Sam.")
print("My favorite color is blue.")
print("My favorite animal is a fox.")
```

🏆 Victory Moment

You just wrote the same first line of code that programmers all over the world write when they learn to code:

```
print("Hello, world!")
```

 . Welcome to the world of Python coders!

🎉 Coming Up Next

In Lesson 2, you'll learn about **variables** — special little boxes that can hold information, like your name or your score, so the computer can remember it and use it later!
